1-----

**We have two heat transfers :**

**Convection** - Which is the heat transfer between a fluid and a solid

**Conduction**- Which is the heat transfer inside the solid

Example of convection and conduction is that - Inside a wall we have Conduction and outside we have **Convection**

**So when we need to find the temperature of the wall and not the temperature inside we have to combine convection and conduction**

We have two types of convection, which are : **Natural and Forced**

The rate of convective heat transfer depends on :

- Variation of the heat
- Speed of air (velocity of liquid or gas)
- Kind (type) of liquid or gas

Newtons Law of Cooling

$$Q_{\text{conv.}} = h \times A_s \times (T_s - T_{\infty})$$

Temp. of the surface  $T_s$  and Temp. of the room inside the room  $T_{\infty}$

$$R_{\text{conv}} = \frac{1}{h \times A_s}$$

According to this formula the higher the air the less resistant (higher the  $h$  less resistance we have), because resistance  $R$

Is not proportional to  $h$

$$Q = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{total}}}$$

$$R_{\text{total}} = R_{\text{con1}} + R_{\text{wall}} + R_{\text{con2}} = \frac{1}{h_1 A} + \frac{L}{k A} + \frac{a}{h_2 A}$$

$$R_g = \frac{L}{k \times A}$$

**The glass doesn't have a big role in heat transfer (thermal resistance of convection-glass is very small compared to conduction - glass and air), so if we raise the thickness  $L$  still the same**

temperature goes inside or a very slight difference which is not to be considered.

2-----

The reason I resulted on wrong answer was the problem of calculation (Math part ), the other part of the assignment went well .

3-----

Consider a 0.8-m-high and 1.5-m-wide double-pane window consisting of two 6-mm-thick layers of glass ( $k = 0.78 \text{ W/m} \cdot ^\circ\text{C}$ ) separated by a 13-mm-wide stagnant air space ( $k = 0.026 \text{ W/m} \cdot ^\circ\text{C}$ ). Determine the steady rate of heat transfer through this double-pane window and the temperature of its inner surface.

Take the convection heat transfer coefficients on the inner and outer surfaces of the window to be  $h_1 = 10 \text{ W/m}^2 \cdot ^\circ\text{C}$  and  $h_2 = 40 \text{ W/m}^2 \cdot ^\circ\text{C}$ , which includes the effects of radiation.

$$A = 0.8\text{m} \times 1.5\text{m} = 1.2 \text{ m}^2$$

$$R_{\text{con1}} = \frac{1}{h_1 \times A} = \frac{1}{10 \times 1.2} = 0.0833^\circ\text{C/W}$$

$$R_{\text{con2}} = \frac{1}{h_2 \times A} = \frac{1}{40 \times 1.2} = 0.0208^\circ\frac{\text{C}}{\text{W}}$$

$$R_{\text{glass}} = \frac{1}{k_{\text{glass}} \times A} = \frac{0.006}{0.78 \times 1.2} = 0.0064^\circ\frac{\text{C}}{\text{W}}$$

$$R_{\text{air}} = \frac{1}{k_{\text{air}} \times A} = \frac{0.013}{0.026 \times 1.2} = 0.4167^\circ\frac{\text{C}}{\text{W}}$$

$$R_{\text{tot}} = R_{\text{con1}} + R_{\text{glass1}} + R_{\text{air}} + R_{\text{glass2}} + R_{\text{con2}} = 0.0833 + 0.0064 + 0.4167 + 0.0064 + 0.0208 = 0.5336^\circ\frac{\text{C}}{\text{W}}$$

$$Q = \frac{T_{\infty 1} - T_{\infty 2}}{R_{\text{tot}}} = \frac{20 - (-10)}{0.5336} = \frac{30^\circ\text{C}}{0.5336^\circ\text{C/W}} = 56.221\text{W}$$

$$Q = \frac{T_{\infty 1} - T_1}{R_{\text{con1}}} =$$

$$T_1 = T_{\infty 1} - Q \times R_{\text{con1}} = 20^\circ\text{C} - 56.221\text{W} \times 0.0833^\circ\text{C/W} \approx 15.3^\circ\text{C}$$
